### 1.0 Introduction

An operating program accepts as input an essay of up to 300 words in length, and yields as output an essay-type paraphrase that is a monredundant summary of the content of the source text.

Although no transformations are used, the content of several sentences in the input text may be combined into a single sentence in the output. The format of the output essay may be varied by adjustment of program parameters. In addition, the system occasionally inserts subject or object pronouns in its paraphrases to avoid repetitious style.

The components of the system include a phrase structure and dependency paragraph, a routine for establishing dependency links across sentences, a program for generating coherent sentence paragramses randomly with respect to order and repotition of source text subject matter, a control system for determining the logical sequence of the paraphrase sentences, and a routine for inserting pronouns.

The present version of the program requires that andividual word class assignments be part of the information; pplied with a source text, and also, that the garamatical tructum of the atences in the source conform to the limitations of the parsing system.

### 2.0 Dependency-Phrase Structure Parsing System

The parsing system used in the automatic essay writing experiments performed a phrase structure and dependency analysis simultaneously. Before describing its operation it will be useful to explain the operation of a typical phrase structure parsing system.

Cocke of IBM, Yorktown, developed a program for the recognition of all possible tree structures for a given sentence. The program requires a grammar of binary formulas for reference. While Cocke never wrote about the program himself, others have described its operation and constructed grammars to be used with the program. 1,2

The operation of the system may be illustrated with a brief example. Let the grammar consist of the rules in Table 1; let the sentence to be marsed be:

# A B C D

The grammar is scanned for a match with the first pair of entities occurring in the sentence. Rule 1 of Table 1,

A + B = P. amplies. Accordingly A and B may be limited together in a tree structure and their limiting node labeled P.

But the next pair of elements,  $\mathcal{L}+C$ , is also in Table 1. This demands the analysis of an additional tree structure.

July 21, 1964

SP-1602/001/00

5. S + D = T

6. R + D = U

# Table 1

Illustrative hules for Cocke's Parsing System

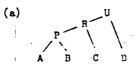

These two trees are now examined again. For tree (a), the sequence P+C is found in Table 1, yielding

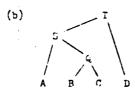

For tree (b), the pair A+Q is found in Table 1, but not the sequence Q+D. The result here is:

Further examination of tree (a) reveals that R+D is an entry in Table 1.

In true (t), ' + D is found to be in Table ::

The analysis has justed two possible tree structures for the

sentence, A B C D. Depending upon the grammar, analysis of longer sentences might yield hundreds or even thousands of alternate tree structures.

Alternatively, some of the separate tree structures might not lead to completion. If grammar rule 6 of Table 1, R + D = U, were deleted, the analysis of sentence (a) in the example could not be completed. Cocke's system performs all analyses in parely and saves only those which can be completed.

The possibility of using a parsing grammar as a generation grammar is described in section 3.

2.1 Phrase Structure Parsing with Subscripted Rules

The phrase structure parsing system devised by the author makes use of a more complex type of grammatical formula. Although the implemented system these recognised more than one of the possible tree structures for a given sentence (multiple analyses are possible with program modification) it does contain a device that is an alternative to the temporary parallel analyses of trees that cannot be completed.

The grammar considers of a set of subciripted philose structure formulas as for example, in Table 2. Here 'N' represents a norm of noun phrase class, 'V' a verb or verb phrase class, 'Prep' a preposition class, 'Mod' a prepositional phrase class, 'Adv' an adjective class, and 'S' a sentence class. The subscripts determine the order and limitations of application of these rules when generating as well as

1.  $Art_0 + N_2 = N_3$ 

2.  $Adj_0 + N_2 = N_3$ 

3. N<sub>1</sub> + Mod<sub>1</sub> = N<sub>1</sub>

4. V<sub>1</sub> + N<sub>2</sub> = V<sub>2</sub>

5. Prep<sub>0</sub> + N<sub>3</sub> = Mod<sub>1</sub>

6.  $N_3 + V_3 = S_1$ 

Table 2

Phrase Structure Rules

parsing. The use of the rules in parsing may be illustrated by example.

Consider the sentence:

'The fierce tigors in India eat meat.

Assuming one has determined the individual parts of speech for each word:

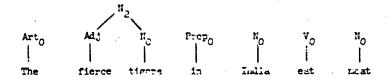

The parsing rethod requires that these grammar codes be examined in pairs to see if they occur in the left half of the rules of Table 2. If a pair of grammar codes in the sentence under analysis matches one of the rules and at the same time the subscripted of the components of the Table 2 pair are greate, then or equal to those of the corremonding elements in the pair in the sentence, the latter pair may be connected by a single node in a tree, and that node labeled with the code in the right half of the rule in Table 2.

Going for left to right (one might start from either direction), the first pair of codes to be checked in  $\operatorname{Art}_0$  +  $\operatorname{Art}_0$ . This sequence does not occur in the left half of thy rule.

The next pair of ordes is  $\mathrm{Ad}_{3} + \mathrm{H}_{0}$ . This pair matches the left half of rule 2 in Table 2,  $\mathrm{Ad}_{3} + \mathrm{H}_{2} + \mathrm{H}_{2}$ . Here the subscripts in the rule are greater than or equal to lastic counterparts in the sentence under analysis. Part of a tree may now be drawn.

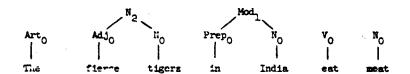

SP-1602/00., '00

July 2, 1964

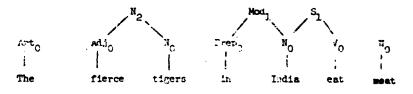

The next pair of codes to be searched for is  $\mathbb{N}_0$  + Prep<sub>0</sub>. This is not to be found in Table 2.

The following pair,  $Prep_0 + N_0$ , fits rule 5; Tabl. 2,  $Prep_0 + N_3 = Mod_1$ . The subscript rules are not violated, and accordingly, the sentence structure now appears as:

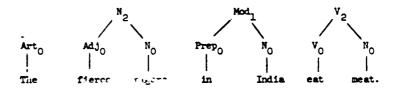

The next pair of codes,  $N_0 + V_0$  also appears in Table 2,  $N_3 + V_3 = S_1$ . But if these two terms are united, the  $N_0$  would be a member of two units. This is not permitted, e.g.,

When a code seems to be a matter of more than one higher unit, the unit of minimal rank is the one selected. Lank is determined

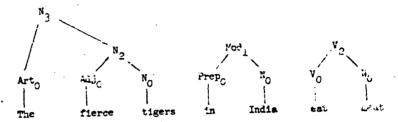

by the lowest subscript if the codes are identical. In this case, where they are not identical,  $S_1$  (sentence) is always higher than a Mod $_1$  or any code other than another sentence type. Accordingly, the union of  $N_0 + V_0$  is not performed. This particular device is an alternative to the temporary computation of an alternate tree structure that would have to be discarded at a later stage of analysis.

The next unit,  $V_0 + N_0$ , finds a match in rule k > 1 the 2,  $V_1 + N_2 = V_2$ , yielding:

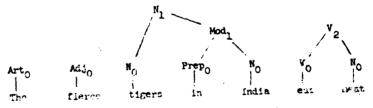

One complete pass has been made through the sentence. Successive passes are made until no new units are derived. On the second pass, the pair  ${\rm Art}_0 + {\rm Adj}_0$ , which has already been rejected, is not considered. However, a new pair,  ${\rm Art}_0 + {\rm N_2}$  is row found in rule 1 of Table 2,  ${\rm Art}_0 + {\rm N_2} = {\rm N_3}$ .

The tree now appears as:

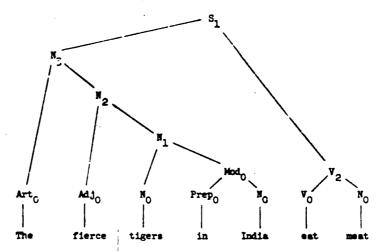

Continuing, the next pair accounted for by Table 2 is  $N_0 + Mod_1$ , which is within the domain of rule 3,  $N_1 + Mod_1 = N_1$ . Here the subscripts of the grammar rule are greater than or equal to those in the text entities. Now the  $N_0$  associated with 'tiger,' is already linked to an  $Adj_0$  unit to form an  $N_2$  unit. However, the result of rule 3 in Table 2 is an  $N_1$  unit. The lower subscript takes precedence; accordingly the  $N_2$  unit and the  $N_3$  unit of which it formed a part must be discarded, with the result:

On the balance of this scan through the sentence to now scructures are encountered. A subsequent pass will link  $\mathbb{A} \mathbb{I}_0$  to  $\mathbb{N}_1$  producing an  $\mathbb{N}_2$  unit. Eventually this  $\mathbb{N}_2$  unit will be considered for linkage with  $\mathbb{V}_2$  to form a sentence,  $\mathbb{S}_1$ , by rule 6 of Table 2. This like age is rejected for reasons pertaining to rules of precedence.

A subsequent pass links  ${\rm Art}_0$  with this  $N_2$  to form  $N_3$  by rule 1 of Table 2. This  $N_3$  is linked to  $V_2$  by rule 6 of Table 2.

As the next pass violer no changes, the analysis is complete. This particular system, as already horizated, makes no provision for deriving several tree structures for a single sentence although it swoids the problem of temporarily carrying additional analyses which are later discarded.

## 2.2 Dependency

A phrase structure or immediate consultuancy analysis of a sentence may be viewed as a description of the relations among units of varied complexity. A dependency enalysis is a description of relations among simple units, e.g., words. Teacriptions of the formal properties of dependency trees and their relationship to immediate

constituency trees can be found in the work of David Hayes, and Haim Gaifman. For the purpose of this paper, the notion of dependency will be explained in terms of the information required by a dependency parsing program.

The particular system described next performs a phrase structure and dependency analysis simultaneously. The output of the program is a dependency tree superimposed upon a phrase structure.

Fundamentally, dependency may be defined as the relationship of an attribute to the head of the construction in which it occurs. In exocentric constructions, the head is specified by definition. Table 3 contains a set of grammatical rules which are sufficient for both phrase structure and dependency parsing. A symbol preceded by an asteriak is considered to be the head of that construction. Accordingly, in rule 1 of Table 3,  $\text{Art}_{0} + \text{*N}_{2} = \text{N}_{3}$ , the  $\text{Art}_{0}$  unit is dependent on the N<sub>2</sub> unit. In rule 6 of Table 3,  $\text{*N}_{3} + \text{V}_{3} = \text{S}_{1}$ , the V<sub>2</sub> unit is dependent on the N<sub>3</sub> unit.

The method of performing a simultaneous phrase structure and dependency at lysis is similar to the one described in the previous section. The additional feature is the cumulative computation of the dependency relations defined by the rules in the grainer. An example will be helpful in illustrating this point.

6. 
$$*N_3 + V_3 = S_1$$

# Table 3

Dependency-Phrase Structure mulcr

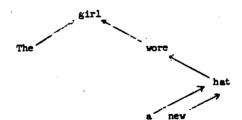

Consider the sentence:

'The girl wore a new hat.'

First the words in the sentence are numbered sequentially, and the word class assignments are made.

Art <sub>O</sub>	N <sub>O</sub>     girl	V <sub>O</sub>	Art <sub>o</sub>	Ad.ic new	No i het	
<u>.</u>	<u>1</u>	<u>2</u>	<u>3</u>	4	. 2	

The sequential numbering of the words is used in the designation of dependency relations. Looking shead, the dependency tree that will be derived will be equivalent to the following:

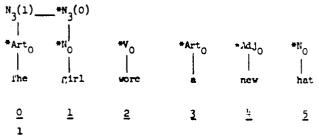

who is the arrows indicate the direction of dependency. Another arrows indicate the direction of dependency analysis is the list fashion--each word being associated with the number of the word it is dependent on.

July 21, 1964

-16-

SP-1609/001/ 1

The	girl	wore	8.	t.ew	hat
<u>o</u>	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>	<u>5</u>
1		ı	Ļ	5	2

All of the information concerning the constructions involving a particular word will appear in a column above that word. Each such word and the information above it will be called an entry. This particular mode of description represents the parsing a likeless place in the actual computer program.

The fact that Art + N $_{0}$  form a unit is marked by the occurrence of  $\sim N_{2}$  at the top of entries 0 and 1. The asterisk preceding the  $N_{3}$  at the top of entry 1 indicates that this entry is a pointed with

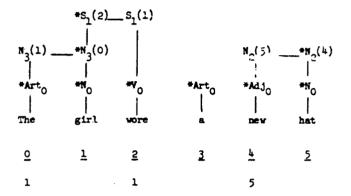

the head of the construction. The astericks associated with the individual word tags indicate that at this level each word is the head of the construction containing it. This last feature is necessary because of certain design factors in the program.

The numbers in brackets adjacent to the N<sub>3</sub> units indicate the respective partners in the construction. Thus the (1) at the top of entry 0 indicates that its partner is in entry 1, and the (0) at the top of entry 1, the converse. The absence of an asterisk at the top of entry 0 indicates that the number in brackets at the top of this entry also refers to the dependency of the English words involved in the construction; i.e., 'The' of entry 0 is dependent on 'girl' of entry 1. This notation actually makes redundant the use of lines to indicate tree structure. They are plotted only for clarity. Also redundant is the additional indicate in the bottom of each entry. This information is tabulated only for clarity.

The next pair of units accepted for by the program is  $Adj_0 + N_0$ . These, according to rule 2 of Table 3, are united to form an  $N_0$  unit.

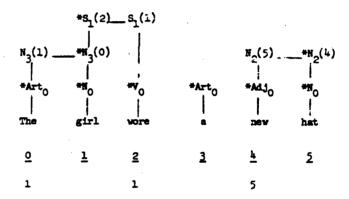

Here 'new' is dependent on 'hat.'

On the next pass through the sentence, the  $N_3$  of entry 1, 'girl,' is linked to the  $V_0$  of entry 2, 'wore,' to form an  $S_1$  unit. It is worth noting that a unit not prefaced by an asterisk is ignored in the rest of the parsing.

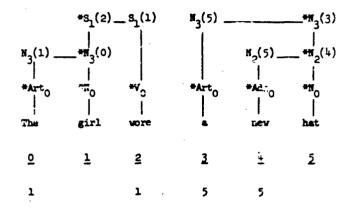

The new dependency energing from this grouping is that of 'wore' upon 'girl.' The Arto of entry 3 plus the N<sub>2</sub> of entry 5 form the next unit combined, as indicated by rule 1 of Table 3. Note that the N<sub>2</sub> of entry 4 can be skipped because it is not preceded by an asterisk. Adjacent asterisked unics are the only candidates for union.

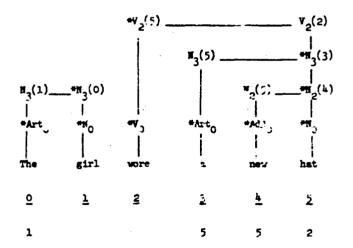

On the next pass through the sentence, the  $N_3$  of entry 1, 'girl,' is linked to the  $V_0$  of entry 2, 'wore,' to form an  $S_1$  unit. It is worth noting that a unit not prefaced by an asterisk is ignored in the rest of the parsing.

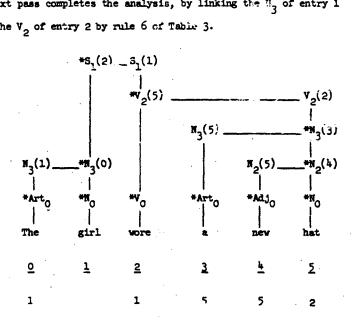

The new dependency courging from this grouping is that of 'wore' upon 'girl.' The Art<sub>0</sub> of entry 3 plus the N<sub>2</sub> of entry 5 form the next unit combined, as indicated by rule 1 of Table 3. Note that the N<sub>2</sub> of entry 4 can be skipped because it is not preceded by an est-risk. Adjacent asterisked units are the only candidates for union.

 $O_{11}$  the next pass through the sentence, the  $V_{0}$  of entry 2 is linked to the  $N_{3}$  of entry 5 to form, according to rule 4 of Table 3, a  $V_{2}$  unit. The  $S_{1}$  unit, of which the  $V_{0}$  is already a part, is deleted because the  $V_{0}$  grouping takes precedence. The result is:

The next pass completes the analysis, by linking the  $\mathbb{S}_3$  of entry 1 with the  ${\rm V}_2$  of entry 2 by rule 6 of Table 3.

Note again that the dependency analysis may be read directly from the phrase structure tree; the bracketed digit associated with the top unasterisked phrase structure lobel for each ontay indicates the dependency of the word in that entry.

The only entry having no unasteriskal form at the top is 1. This implies that 'girl' is the head of the sentence. This choice of the main noun subject instead of the main very as the sentence head is of significance in generating coherent discourse. The reasons for this are indicated in section 3.2.

## 3.0 Generation

The discussion of generation is concerned with the production of both nonsensical and coherent discourse.

### 3.1 Grammatically Correct Nonsense

The generation of grammatically correct nonsense may be accomplished with the same type of phrase structure value as in Table 2, 3 and 4. (The asterisks in Table 3 are not pertinent at the presentation.) A computer program implementating a phrase structure generation grammar of this sort has been built by Victor Yngve. 5

The rules in Table 4 contain subscripts which, as in the parsing system, control their order of application. The rules may be viewed as rewrite instructions, except that the direction of rewriting is the reverse of that in the parsing system.

Starting with the symbol for rentence,  $S_1$ ,  $N_3 + V_3$  may be derived to rule 6 of Table 4.

Note that a tree structure can be generated in training the history of the rewritings. Leftwest nodes are supposed first. The  $N_3$  unit may be replaced by the left half of rule 1, 2 or 3. If the supercript of the N on the right half of these rules were greater than

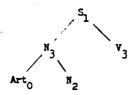

5. 
$$Prep_0 + N_3 = Mod_1$$

6. 
$$N_3 + V_3 = S_1$$

# Table 4

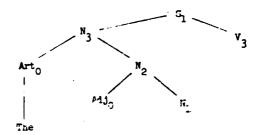

Illustrative Generation Grammar Rules

3, they would not be applicable. This is the reverse of the condition for applicability that pertained in the parsing system. Assume rule 1 of Table 4 is selected, yielding:

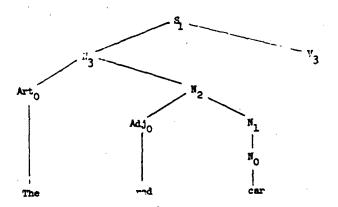

A node with a zero subscript cannot be further expanded. Althat remains is to choose an article, at random, say 'the.' The  $N_2$  unit can still be expanded. Note that rule 1 is no longer applicable because the subscript of the right hand member is greater than :

Suppose rule 2 of Table 4 is selected, yielding:

Now an adjective may be chosen at random, cay, 'red.' The only expansions of  $N_1$  are by rule 3 of  $2\pi$  in  $3\pi$ , or rule 7, which makes it a terminal node. Note that rule 3 is recursive: that is, it may be used to rewrite a node repeatedly without reducing the value of the

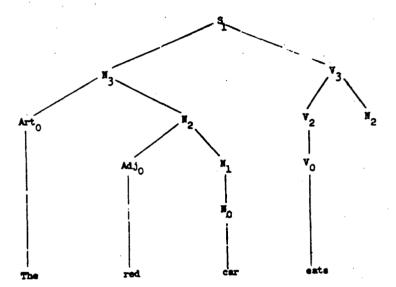

subscript. Accordingly an adjective string of indefinitely great length could be generated if rule 3 were chosen repeatedly. For the sake of brevity, next let rule 5 of Table 4 to scleeted. A noun may now be chosen at random. Say, 'car,' yielding:

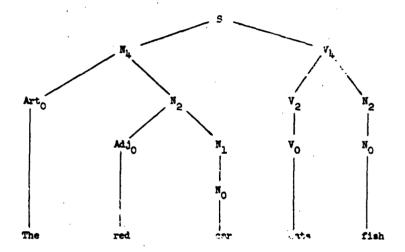

Let the  $V_3$  be written  $V_1 + N_2$  by rule 4 of Table 4 and that  $V_1$  rewritten as ", by rule 8 of Table 4. Let the verb chosen for this terminal node be 'eats.'

July 21, 1964

The only remaining expandable node is  $N_2$ . Assume that  $N_0$  is selected by rule 7. If the noun chosen for the terminal node is 'fish' the final result is:

With no restrictions placed upon the selection of vocabulary, no control over the semantic coherence of the terminal sentence is possible.

## 3.2 Coherent Parcourse

The output of a phrase structure generation grammer combe limited to coherent discourse under contain conditions. In the vocabulary used is limited to that of some source text, and if it is required that the dependency relations in the order devicences not differ from those present in the source text, then the comput sentences will be

coherent and will reflect the meaning of the source text. For the purpose of matching relations between source text and output text, dependency may be treated as transitive, except across prepositions other than 'of' and except across verts other than forms of 'to be.'

A computer program which produces coherent sentence par\_phrases by monitoring of dependency relations has been described elsewhere. 6,7 An example will illustrate its operation. Consider the text:

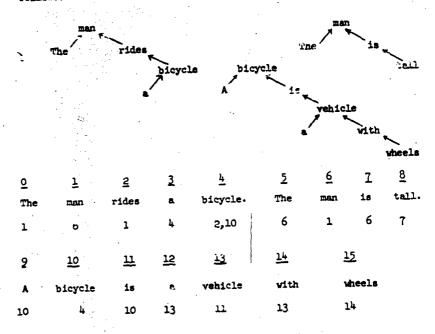

'The man rides a bicycle. The man is tall. A bicycle is a vehicle with wheels.'

Assume each word has a unique grammatical code assigned to it.

	The   Art	men       N	rides     	a   Art	bicycle      N	
	The	man     	1s     	- J		
A   Art	bicycle         	1s     	a       Art	vehicle     	with Prep	wheels

A dependency analysis of this text can be in the form of a network or a list structure. In either case, for purposes of

paraphrasing, two-way dependency links are assumed to exist between like tokens of the same noun. A network description would appear as follows:

The paraphrasing program described would begin with the selection of a suntence type.

This generation program, in contrast with the method described above, chooses lexical items as soon as a new slot appears; for example, the main subject and verb of the sentence are selected now, while they are adjacent in the sentence tree. Assume that 'bicy: $12^4$  is selected as the noun for  $N_{\rm q}$ .

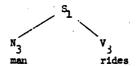

It is now necessary to find a verb directly or transitively dependent on 'bicycle.' Inspection of either the network or list representation of the text dependency analysis shows no verb dependent on 'bicycle.' the computer determines this by treating the dependency analysis as a maze in which it seeks a path between each week token and the word 'bicycle.' Accordingly, the computer program requires that another noun be selected in its place; in this case, 'man.'

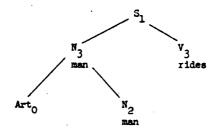

The program keeps track of which takes of import is selected.

It is now necessary to choose a verb dependent on 'man.' Let 'rides' be chosen.

Now the  $N_{\rm q}$  may be expanded. Suppose rule 1 of Table  $4~{\rm km}_{\odot}$   $^{-1}{\rm Sec}$ 

Not 'hat 'man' is associated with the new noun phrese node, N2.

It is now necessary to select an article dependent on 'man.'

Assume 'a' is selected. While a path 'a' to '.....' does seem to

exist in the dependency analysis, it crosses 'rides,' which is a

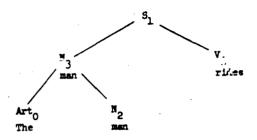

member of a verb class treated as an intransitive link. Accordingly,

'a' is rejected. Either token of 'the' is acceptable, however.

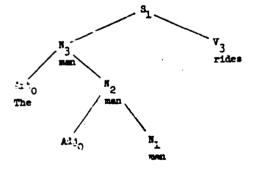

(Note unat for simplicity of presentation no distinction among verb

classes has been made in the rules of Tables 7 - 4.)

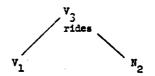

July 21, 1964

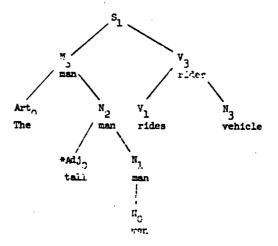

The 'Art  $_0$ ' with a zero subscript cannot be further expanded. Let the 'N  $_2$ ' be expanded by rule 2 of Table 4.

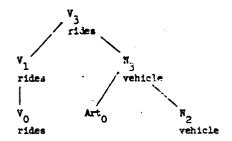

Let ' $N_0$ ' be chosen as the next expansion of  $N_1$ , by rule 7. Now the only node that remains to be expanded is  $V_3$ . If rule 4 of Table 4 is chosen, the part of the tree pertinent to 'rides' becomes:

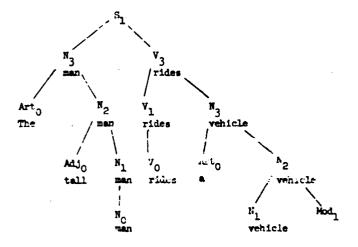

A noun dependent on 'rides' must now be found. Either token of 'man' would be rejected. If 'vehicle' is chosen, a path does exist that traverses a transitive verb 'is' and two tokens of 'bicycle.'

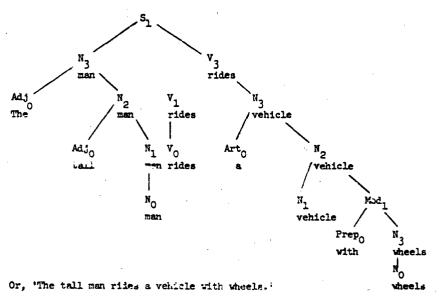

Let ' $V_0$ ' be chosen as the rewirting of  $V_2$  by rule 8 of Table 4, and let the  $N_3$  be rewritten by rule 1 of Table 4. The pertinent part of the true now appears as follows:

Assume that 'a' is chosen at the arricle and that N $_2$  is rewritten as N $_1$  + Mod $_1$  by rule 3 of Table 4. The result is:

The Mod<sub>1</sub> is purely a slot marker, and no vocabulary item is selected for it. If the Mod<sub>1</sub> is rewritten  $Prep_0 + N_3$  by rule 5 of Table 4, 'with' would be selected as a preposition dependent on 'vehicle,' and 'wheels' as a noun dependent on 'with.' After the application of rule 7, the  $N_4$  would be rewritten  $N_0$ , completing the generalion.

In cases where no word with the required dependencies the befound, the program in some instances deletes the pertinent portion of the tree, in others, completely about the generation process. The selection of both vocabulary items and structural formulas is done randomly.

### 4.0 An Essay Writing System

Three computer programs were described in sections 2 and 3. The first performs a unique dependency and phrase structure analysis of individual sentences in written English text, the locabulary of which has received unique grammar codes. The power of this program as limited to the capabilities of an extremely small recognition grammar.

The second program generates grammatically correct sentences without control of meaning. The third program consists of a version of the second program coupled with a dependency monitoring system that requires the output sentences to preserve the transitive dependency relations existing in a source text. A unique dependency analysis covering relations both within and among text sentences is provided as part of the input. The outputs of this third program are grammatically imprect, coherent paraphrases of the input text which, however, are random with respect to sequence and repetition of source text content.

What is called an 'ecsay' writing system in this section consists of all the programs described earlier, plus a routine for assigning dependency relations across sentences in an imput tent and a routine which insures that the paraphrase contences will name to a married sequence and will not be repetitions with respect to the source text content. Still another device is a contine that permits the generation of a paraphrase around an outline supplier with a larger body of text. In addition, several generative devices have been added: routines

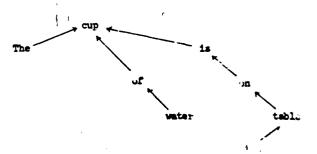

for using subject and object pronouns even though none occur in the input text, routines for generating relative clauses, although, again, none may occur in the input text, and a routine for converting source text verbs to output text forms ending in '-ing.'

## 4.1 Dependency Analysis of an Entire Discourse.

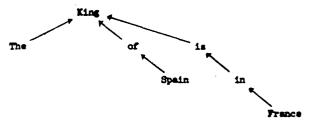

and phrase structure analysis of individual sentences, " is necessary for another program to emalyze the text as a unit to assign dependency links across sentences and to alter some dependency relations for the sake of coherent paraphrasing. The present version of the program assigns two-way dependency links between like tokens of the same noun. A future version will be more restrictive and assign such links only among tokens having either similar quantifiers, determiners, or subordinate charges, at which are determined to be equatable by special semantic rules. This is necessary to insure that each token of the same noun has the same real world referent.

While simple dependency relations are sufficient for paraphrasing the artificially constructed texts used in the experiments described in this paper, paraphrasing of correstricted English text would demand special rule revisions with respect to the direction and integerous of the dependency relation. The reason for this is easily understood by a simple example familiar to transformationalists.

'The cup of water is on the table'

'The King of Spain is in France'

The parsing system would yield the same type of analysis for each sentence. Yet it would be desirable to be able to paraphrase the first sentence v. h:

"The water is on the table"

without the possibility of paraphrasing the second sentence with

"onain is in F. ance."

Accordingly, a future modification of the routine described in this section would, after noting the special word classes involved, assign two-way dependency links between 'cup' and 'of' and also between 'of' and 'water,' but take no such action with words 'King,' 'of,' and 'Spain' in the second sentence. This reparsing of a persing has significance for a theory of grammar, and its implications with respect to stratificational and transformational models is discussed in section 5.

Control over sequence and nonrepetition of the paraphrase sentences is obtained through the selection of an essay format. The format used in the experiments performed consists of a set of paragraphs each of which contains only sentences with the same main subject. The ordering of the paragraphs is determined by the sequence of nouns as they occur in the source text. The ordering of sentences within each paragraph is partially controlled by the acquence of verbs as they occur in that text.

Before the paraginasing is begun, two word lists are compiled by a subroutine. The first list contains a totum of each source text noun that is not dependent on any noun or noun token occurring before it in the text. The tokens are arranged in source text or text. The second list consists of every token of every root in the text, in semience.

The first noun on the list is automatically selected as the main subject noun for each sentence that is to be generated. As many generations are attempted as there are verbs on the vert list. The main verb for each such sentence generation attempt is taken in sequence from those on the list. Once a sentence is successfully generated, the token of the verb used is deleted from the verb list. Monsequential use of verbs can occur in relative clauses or rodifying phrases. in these instances also, the verbs or verb stem tokens used are deleted from the word list. When every verb on the list has been tried as the main werb for a particular main subject noun, a new paragraph is begun and the next noun on the list becomes the main subject for each sentence. The process is continued until the noun list is exhausted. It may happen that some nouns do not appear as subjects of paragraphs even though whey uppear on the noun list, because they do not occur as main subjects in the source text. (This projetive was arbitrarily selected as suitable for testing the program; other formats for essay generation can be implemented.)

The use of an outline as the basis for prierating in essay from a larger body of text is commuplished simply; the boundary between the cutline and the main body of text the follows is marked. The noun list is limited only to those nouns occurring in the outline. The torbs selected still include those is the main text as well as the ones in the outline. Theoretically, the main text could consist of a large library; in that case the outline might be viewed as an

information retrieval request. The output would be an essay limited to the subject matter of the outline but drawn from a corpus indefinitely large in both size and range of subject matter.

4.3 Generation of Word Forms Not Present in the Source Text

Earlier experiments indicated that in many instances reasonable paraphrases could be performed with the method described herein if the dependency relations held only among stems rather than among full word forms and if the stems were subsequently converted. Norm. of the proper grammatical category. The present system will accept a verb form with proper dependency relations and use it in a form ending in '-ing' when appropriate.

Relative clauses may be generated even though no relative pronouns occur in the source text. Where the generation process requires
a relative pronoun, 'who' or 'which' is inserted into the proper slot
depending on the graier of the appropriate antecedent. All the decraptors of the antecedent are then assigned to the relative pronoun.
As far as the operation of all programs is concerned, the pronoun is
its antecedent. Accordingly, if a routine is to inquire whether a
particular vero is dependent on a relative pronoun, the request is
formulated in terms of the verb's dependency on the antechdent of
the relative pronoun.

The system may also generate subject and object pronouns although subjects and object pronouns is accomplished by separate contines. Subject pronouns

may be used randomly at a frequency that may be controlled by input parameters. After the occurrence of the first sentence in a paragraph, a subject pronoun of appropriate gender and number may be used as the main subject of subsequent sentences within the paragraph if program generated random numbers fall within a specified range.

The occurrence of an object pronoun of appropriate number and gender is obligatory whenever a nonsubject noun would normally be identical with the last normain subject noun used. A special storage unit containing the last normain subject noun used gives the program easy recognition of the need for a pronoun.

#### 4.4 Computer Generated Essays

A number of essays were produced from varied texts, all of which were specially constructed so as to be suitable for parsing by a small dependency one of the structure grammar. The pairsing recognition grammar is contained in Table 5. (Because the material covered forms a related whole, Table 5 and all subsequent tables are gathered in an appendix at the end of this document.) The generation grammar is shown in Table 5. The recognition grammar is more possible than the generation grammar. The limit input text made no use of an outline; more exactly, because the program outlingates the presence of or outline, the entire text was its own outline. Input Text I is contained in Table 7, part 1. Its essay paraphrets, Catput Text I, is contained in Table 7, part 2. Nove that the generation rules used in producing Output Text I do not contain the rule for producing forms ending in '-ing.'

The use of this rule and the associated device for converting verb forms ending in '-ing' is illustrated in Output Texts III and IV, which appear in Tables 10 and 11.

Unambiguous word class assignments were part of the input data.

As an example, the first sentence of Input Text I, Table 7, was coded:

Clever (adj.) John (noun, masc., sg.) met (varb, 3rd pers. sg.)
Mary (noun, fem., sg.) in (prep.) the (art) park ( m. neut. sg.).

Capital letters were indicated by a '+' sign preceding the first letter or word because a computer does not normally recognize such forms. The presence of an initial capital letter with a word could 'noun' provided the program with information sufficient to distinguish such forms as belonging to a separate class. Two verb classes were distinguished in the recognition grammar, forms of 'to be' and all others; also, two preposition classes were established, 'of' and all others. Ad how word class assignments were made in the case of 'married' in Input Text I, Table I, which was treated as a noun, and the case of 'fl renco' in Input Text II, Table 9, which was labeled an adjective. In each case this was done in order to avoid a more complicated generation grammar. A price was paid for this simplification as can be seen in the phrase 'Flamenco Welen' generated in Gutput Text II, Table 9. The uncapitalized form of 'beautey' which appears in severe!

of the later paraphrases is not a typographical error, but rather is intended to reflect the use of capitalization to distinguish a separate word class. In order not to assign 'benthey' to the same class as 'John' it was left uncapitalized. (The device is not wholly adequate.) The noun classes differentiated by the presence or absence or prefixed '+' were manipulated directly within the program rather than by special rules for each class. The program prevented a form prefixed by a '+' from taking an article and from being followed by a form ending in '-ing.'

It should be noted that the spacing of the output texts in Table 7 and beyond is edited with respect to spacing within paragraphs. Only the spacing between paragraphs is similar to that of the original output.

Table 8 contains an essay paraphrase generated with the requirement that only the converse of Input Text I dependencies be present in the output.

## 5.0 Discussion

There are several comments that can be made about the essay writing program with respect both to the functioning of the programs and to the implications for linguistic theor, suggested by the results.

# 5.1 Program

The compiled program occupies shows 12,000 registers of Philos 2000 core storage, approximately 8,000 registers of which are devoted to tables. The JOVIAL program contains approximately 750 scatements. Because of space limitations, the largest text the system can paraphrase is 300 English words, counting periods as words.

One early version of the system took an hour and a half to paraphrase 150 words of text; various attempts were made to control this processing time. Two programming devices used in this effort are described below.

Becames the generation process involves a search of a network-the dependency structure of the text--the processing time would be expected to increase exponentially with text size. The : " factors that control the exponential rate of growth, besides text length, are the amount of connectivity among words and the syntactic complexity required of the sentences generated. Text that seldom repeats tokens of nouns would yield a nearly linear network, and the exponential increase of processing time per word with respect to length would not notice: 'a for short texts. However, the texts paraphrased in this paper had a fairly high frequency of repetition of noun tokens. The nc -rk representing the dependencies was made relatively linear by having the program link a noun token only to its immediately preceding : token. Because dependency is transitive, all computed results were the same as if - with token of a noun were linked to every other token of the same nour. Because or this linking convention, the dependency network was sufficiently linear to be , the rate of impresse linear with respect to text length, at least for the examples used in this parer.

Another device contributing to the reduction of processing time is tree pruning. The program generates a tree. If a subconstruction is initiated that cannot be carried to completion, it is often deleted without abandonment of the remainder of the generation tree. Unrealizable adjectives are among the units pruned. The addition of a routine to prune modifying phrases reduced the processing line to approximately 10% of the time required without the section when the system was set to favor text with numerous modifying phrases.

The average time for generating an essay from an input of about 150 words is now 7 to 15 minutes, depending on the syntactic complexity required of the output. The processing time for producing a text from a 50-word source is about 15 minutes. From these figures it can be seen that the processing time per word increases linearly with the length of the text. Is seconds per word for a 50-word text input, about 45 seconds a word for a 150-word text input.

#### 5.2 Theoretical Implications

The present version of the automatic essay writing system could not operate satisfactorily with unrestricted English text as input. For it to do no would require refinement of the dependency enalysis, which was derived from immediate constituency considerations. As indicated earlier, reassignment of dependency links on the basis of the presence of numerous special word classes would be necessary. The problem presented by the necessity for recognizing multiple parsings of English sentences remains as enother major hurdle.

The fact that verbs having appropriate dependency relations in source texts were satisfactorily used as '-ing' forms in paraphrases suggests a more general system in which input text words belonging to a variety of grammatical classes could be converted to new forms in output text by the appropriate application of what might be described as inflectional and derivational processes.

Such a system would have significance for liministic theory.

Even the system described earlier accomplishes the work of a number of transformations without using any. While a transformational grasmar might be used to produce paraphrases beyond the scope of this system, the work of many transformations can be accomplished with a simpler conceptual framework. A transformation is an empirical generalization about a relation hip between strings. In contrast, a transitive interpretation of dependency relations can often be used to predict the relationship a transformation represents.

Even though the essay writer described in this paper is an applied system, any complete theory of grammar should be able to account for its operation. I do not believe that transformational theory can do so.

A stratificational model of language might have more explanatory power. If, as in Sydney Lamb's modul, 8,9 one posits the existence of a memoric stratum above a learning one, an explanation can be provided. Dependency relations may be viewed as a maxemic counterpart of tactic

relations among sememes. A dependency structure defining relations among lexemic units would have many very similar counterparts on the sememic stratum, somewhat as a listing of alloworphs in a language might resemble a listing of morphemes. The experiments described operated under conditions where the dependency structure was a close approximation to the semotactic structure which is posited as being the proper domain for manipulating meaning relations be. One text and another. The first dependency analysis is analogous to lexotactic analysis. A refinement of this analysis might correspond to a semotactic analysis. Conceivably, a sufficiently refined system might come to resemble a dynamic implementation of a stratificational model.
